

# Traverse: Distributed, Scalable, High-availability Architecture

Kaseya Traverse is a breakthrough business service monitoring and network performance management application that provides real-time visibility into the health of IT services. Traverse provides a correlated and business-oriented view of the IT infrastructure, and links the underlying IT infrastructure to the supported business services and processes. Traverse's innovative Business Service Container technology enables IT and business personnel to create unique virtual views of the IT infrastructure. Traverse can monitor, in real-time, millions of metrics from tens of thousands of end points and devices.

### The Database Bottleneck Challenge

A key limitation of most management systems is the existence of a centralized database for processing performance data. Even if the collection of data is managed by distributed components, the solutions invariably require centralization of the data for processing and alert generation. For large infrastructures, this introduces a significant performance bottleneck. The multiplier effect of the amount of data that needs to be processed as new devices are added is enormous. For each new device, hundreds of new metrics may need to be captured on a recurring frequency. For mission-critical systems, the refresh frequency for performance data could be quite high. An environment of ten thousand devices, for example, may easily generate millions of metrics every few minutes. Capturing and processing these metrics in a single centralized database puts immense pressure on the overall application, creating a significant performance bottleneck.

### Fully Distributed, Real-time Architecture

Traverse is built on a powerful, fully-distributed architecture featuring two primary components, Data Gathering Engines (DGE) and the Business Visibility Engine (BVE). What is unique about Traverse is that there is no centralized data warehouse, unlike any other monitoring solutions that have to centralize their data to perform analysis, generate alarms and produce reports. Traverse has distributed collection capability AND a distributed database architecture, which allows the system to scale to extremely large environments with standard hardware.

#### Data Gathering Engines (DGEs)

Traverse's DGEs are independent data gathering element that collect, process, analyze, and store performance data locally from networks, devices, servers and applications. DGEs collect the alarms, events, and polls from the various infrastructure elements such as servers, routers, and applications. Each DGE has its own distributed relational database. Unlike other architectures, there is no central database into which all DGEs have to feed data into for reporting purpose. Each DGE collects data according to the definitions it has been given from the object store. These definitions include which

Kaseya Traverse Cloud Architecture

devices it should monitor, how frequently it should monitor such devices, and what it should do with the results.

Traverse's DGE Extensions enable capturing performance data from closed or secure networks by eliminating the need for inbound connections from the primary data aggregation point. Furthermore, the DGE Extensions do not require any static IP addresses, and thus new data gathering elements can be added quickly whenever and wherever needed. The DGE Extensions also support monitoring multiple private networks that may have over-lapping IP addresses.

## **Business Visibility Engine (BVE)**

The BVE is a centralized configuration object store that stores metadata about users, permissions, devices, connections, and the correlation between services and underlying infrastructure. The object store allows IT personnel to set up business services and containers, and maintains the data on all thresholds, traps and syslogs. It also maintains application user permissions, definitions of what infrastructure elements are in which business container views, which data gathering elements monitor which infrastructure components, and at what frequency and with which specific queries/tests.

When a user logs in via the Web UI, and the data is automatically fetched from the distributed DGEs and presented in a unified, correlated view. Very little data is transmitted over the WAN. Traverse's web-based reporting and graph generation engine consolidates system and application performance to provide real-time status and historical reports. Traverse BVE is responsible for coordinating information from all the DGEs and providing it to the user ondemand.

## **Distributed Databases and Processing**

Traverse has been architected so that the DGEs are completely independent of each other and are only responsible for their own localized data store. The entire task of correlating the data using the metadata in the configuration database is handled by the BVE.

The BVE then summarizes the multiple results into a consolidated view and presents it to the user. This unique interaction between the BVE and the multiple DGEs is highly efficient. Traverse has been awarded multiple patents on its distributed database architecture, and distributed processing and reporting solution. Most systems require a central database for historical data reporting. This severely limits scalability. Traverse's BVE removes the need for a central database through its coordination of multiple independent DGEs.

## **High Availability Configurations**

Traverse's distributed database and processing architecture supports high levels of fault tolerance and scalability. All of the components in the various tiers are horizontally scalable which is essential for expansion and generation of real-time performance reports. All of the configuration information is stored in the BVE configuration database. On startup, the DGEs connect to the BVE configuration database and download a local copy of their configuration. Any updates made to the BVE configuration database are pushed out in real time to the corresponding DGE. If for some reason the BVE goes offline, the DGE can continue capturing and processing data, and generating alarms.

### **DGE High Availability**

The DGEs are independent, and continue to function even if connectivity between the DGE and BVE is lost. If the DGE were to become isolated, it continues to monitor, process and even generate alarms. When connectivity to the BVE configuration database is restored, the DGE synchronizes its configuration from the BVE and all deletes, adds or updates are propagated to the DGE automatically.

When the production DGE comes back up, it can run in parallel before shutting down the backup DGE. The only caveat is that the performance data collected during this interval will be missing on the production DGE.

If desired, a backup DGE can be installed for each of the production DGEs (N+N redundancy).

Traverse has been awarded multiple patents on its distributed database architecture, and distributed processing and reporting solution.

### **BVE High Availability**

The BVE database can be replicated on multiple servers for fault tolerance. DGEs are able to automatically failover to an alternate BVE database if the primary database is not reachable. The JDBC communication between the DGE and the performance database allows creating such a setup seamlessly by making just a few configuration file changes. Even a simple setup using DNS with low TTLs which allows changing the IP address of the BVE and have all the DGEs or DGE-extensions re-establish their connections to a new BVE server is trivial to setup and very effective because of the Traverse distributed architecture.

Lastly, the Web application and reporting engine also gets all the configuration information from the BVE database server on startup and hence any number of Web application servers can exist behind a load balancer for fault tolerance as well as distributed report processing.

### **Proven Scalability and Reliability**

Hundreds of organizations are leveraging Traverse for true IT business service assurance. Traverse customers include large and medium enterprises, MSPs, utilities, universities and governmental institutions. Some of the installations at Fortune 100 companies are monitoring a million metrics every 5 minutes (over 200 million metrics every day) in addition to syslogs and traps. Traverse is delivering substantial benefits to customers in the areas of massive scalability, cost savings, flexibility, rich reporting and virtualization monitoring.

### **The Bottom Line**

Traverse has a distributed and scalable architecture that has the unique characteristic of not having a centralized data warehouse. Traverse has a distributed collection AND distributed database architecture which allows the system to scale to very large environments with standard hardware. The DGEs are independent data collectors and processing engines (much like the distributed nature of DNS) and only needs to process its local data set. The BVE layer is responsible for correlation and reporting, and as users log in via the Web UI, the data is automatically fetched from the distributed DGEs and presented in unified, correlated views. Traverse's architecture is inherently fault tolerant, and is well suited to monitoring mission-critical, complex, distributed infrastructures.

Traverse is delivering substantial benefits to customers in the areas of massive scalability, cost savings, flexibility, rich reporting and virtualization monitoring.

---

#### **ABOUT TRAVERSE**

Traverse is a next-generation monitoring solution from Kaseya, a global software solution provider with over 10,000 customers globally. Traverse's patented technology offers a distributed, scalable monitoring platform with rich data analytics and unified cloud & network management. Traverse allows enterprises and Managed Service Providers to optimize their IT operations with faster mean time to resolution for slow or failed IT services within their infrastructure. Customers leveraging Traverse include the Fortune 100 as well as small-sized and medium-sized businesses worldwide. For more information, visit [www.traverse-monitoring.com](http://www.traverse-monitoring.com)
